

Vertex UX/UI

As the UX/UI Lead for the Vertex One program, I led the end-to-end design of Honeywell's next-generation toxic gas monitoring system for semiconductor fabs—an evolution of the award-winning Vertex Edge platform. The project integrated hardware, embedded interfaces, and cloud-ready HMI software to improve serviceability, ergonomics, and usability in high-containment environments.

UI/UX Design

I was responsible for designing the new UI for VertexONE which required pixel-perfection and creatively reimagining the product with a new vibrant look and feel that matched the Honeywell brand. I adapted the design system and created components that would work specifically for a large tablet-like interface. The resulting experience was viewed favorably by stakeholders including leadership.

Matt McGlothlin

Point Mapping

Consistency of point mapping since the interaction pattern is similar to PLC config. Therefore user only has to learn the functionality one time.

Search and Filter

Search and filter locations by short description, long description, AZ and PT

Point mapping

Each location displays up to six points with Analyzer # and Point #

Guage Charts

Location detail displays guage chart with alarm thresholds, concentration and any faults highlighted in yellow.

HMI - POINTS, LEGEND AND MODES

FEATURES

Power Status

Header iconography allows user to monitor pump and power status in one glance. Selecting either graphic enables user to manage both.

Legend

New users unfamiliar with the UI can touch info icon for legend that defines point color and icons.

Layout Switcher

Switching between grid, column and single analyzer view gives users more flexibility and options for viewing analyzer status

Icon-assisted Points

Color blind users are able to distinguish between red and green easily with the help of icons

REMOTE MANAGEMENT (MVO2)

FEATURES

Multiple Vertex Overview

See status of all analyzers/points on all Vertex in one screen including alarms, faults and inhibits.

Drill-down Functionality

Select a Vertex and drill down into the analyzers/points for that Vertex in detail.

Responsive User Interface

View and manage each vertex from table or phone without losing important information.

SENSOR (MVO2)

FEATURES

Iconography

NDIR, Chemcassette and ECC icons signify to user which sensor analyzer contains

Legend

Bottom legend displays definitions for each type of sensor when selecting.

Sensor management

Bump and calibration process for ECC and NDIR sensors similar to Midas M.

TGMS INTEGRATION (WIP)

PLC CONFIG

FEATURES

Preset and preview

User can visualize the card preset settings including type and amount as well as interact with tooltips that explain terminology = More efficiency.

Guided Relay Mapping

Mach step is activated in a just-in-time fashion so that the user is never overwhelmed with choices.

Forgivable interface

Every step is reversible in case of mistake and changes are denoted with pending icons so user never loses track of changes.

IDLE SCREEN (WIP)

FEATURES

Auto-logout

Customer is able to configure the logout timeout as well as enabling feature.

At-a-glance status

Customer can view status from a distance and quickly gather information on the current status of Vertex.

OVERALL EXPERIENCE

Continuous UI improvement (Edge > C > One) strengthens Honeywell usability advantage over major competitors like DoD.

USABILITY

Point mapping system increases productivity and improves recognition/recall of point location configurations.

DATA INTEGRITY

Backup and restore prevents data loss and reduces downtime due to unforeseen conflicts.

INTEGRATION

TGMS inhibit timer enables FSE to prevent automatic faults

SAFETY

Disabling auto pump swap prevents potential safety issue when working on backup pump.

screen highlighting Vertex status.

DESIGN

Vertex One Design Workshop – Summary and Outcomes

Held at Honeywell's Lincolnshire headquarters, the Vertex One UX Workshop brought together cross-functional stakeholders from product management, engineering, human factors, and field services to align on the next-generation Vertex One vision. The session focused on reimagining the human-machine interface (HMI) and overall user experience for toxic gas detection in high-risk semiconductor FAB environments. As the UX Design Lead, I helped shape the workshop agenda, methods, and synthesis framework that guided subsequent concept validation at Samsung Austin. The workshop surfaced key challenges in integrating and maintaining Vertex systems, with emphasis on cybersecurity, preventative maintenance, documentation, system upgrades, and service efficiency. Discussions included field service team members for Intel, Samsung, and other partner accounts.

Prework and agenda

The technical support performance analysis revealed key factors affecting customer experience and service efficiency for the Vertex product line. The study identified documentation, software support, and analyzer troubleshooting as the top drivers of customer assistance requests.

Key insights:

- **Documentation issues** account for the highest number of tickets (121) and the most accessed knowledge articles (100+).

Attendees

Prework - Customer Support Tickets

Category	Count

Agenda - Day 1

- Day 1 Session 1** (Jeremy, Steven)
 - End to end services
 - Samsung Taylor visit with Richard notes

- Day 1 Session 2** (Erik, Tao, Siegal)
 - Design details for Vertex One AZ and Rack systems
 - Where we are at with architecture
 - Where we are at with global PDU
 - Modularity of major elements

Feedback - What is meant by modularity?

Optics module could be modular	Modularity might mean that the system can be configured in different ways to meet specific needs.	Modularity means the system can be configured in different ways to meet specific needs.
Modularity means the system can be configured in different ways to meet specific needs.	Modularity means the system can be configured in different ways to meet specific needs.	Modularity means the system can be configured in different ways to meet specific needs.

CTO Guidance

CTO Guidance: The system should be designed to be modular, allowing for easy integration and maintenance. The system should be designed to be modular, allowing for easy integration and maintenance.

- Together, these patterns show that user friction peaks during installation, configuration, and maintenance workflows—especially around software compatibility, optics calibration, and documentation clarity. Streamlining these areas with **improved procedural guidance, interactive digital tools, and enhanced remote diagnostics** could significantly reduce escalation rates and technician downtime.

Over four collaborative workshop sessions, a cross-functional team—including field service engineers, tech support leads, software developers, mechanical and electrical engineers, systems engineers, offering managers, and global fellows—examined the end-to-end customer experience of Honeywell’s gas detection systems.

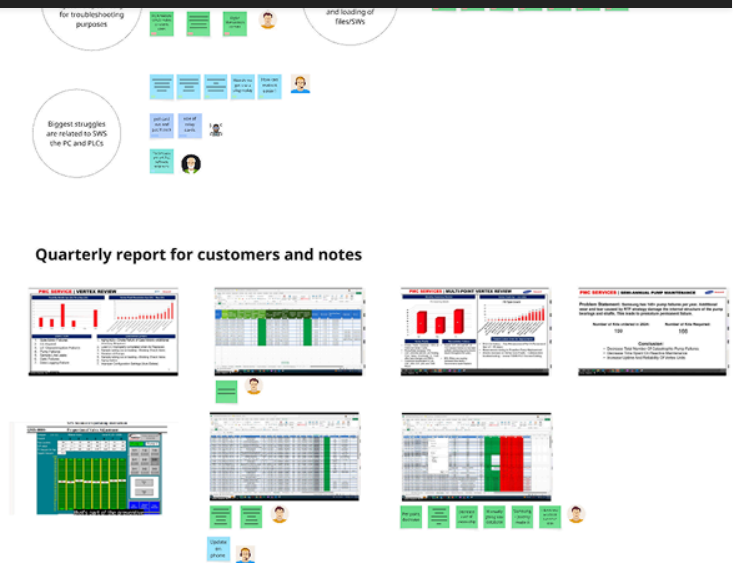

Discussions focused on service inefficiencies, training gaps, and nuisance alarms in semiconductor fabs. Human factors were central, referencing Fitts' Law, ergonomics, and Nielsen Norman heuristics to assess HMI usability. Microsoft Copilot supported synthesis by summarizing transcripts and quotes. A review of the Samsung customer visit highlighted repair turnaround challenges, pump reliability, and system architecture issues, leading to analysis of **PLC configuration**, alarm logic, modular design, and HMI responsiveness.

Clustering and AI synthesis

I organized all notes from the Day 1 and Day 2 workshops, first clustering them by the speaker's name. Then, I used AI to group the notes by keyword and sentiment. Each note is now tagged by both name and keyword, giving us richer context and faster access to insights. From this process, clear themes have begun to emerge, including cybersecurity, hardware and configuration, **maintenance and reliability**, system integration, data management, **user experience**, **operational efficiency**, and **training and support**.

These findings reinforce our initial pre-work and include new insights and anecdotes from FSEs explaining root causes. For example, flow rate fault alarms may result from CC wobble, while frequent downtime and support cases often stem from limited understanding of preventative maintenance.

Additional ideas include improved **in-app documentation**, **diagnostics with recommended actions**, **clearer software versioning**, and **step-by-step guides** for optics cleaning.

Automated reporting could deliver tailored insights for different audiences, while remote troubleshooting and clearer Chemcassette visuals could reduce inefficiencies and miscommunication.

Putting it all together

I gathered all information from workshops, tech support, meetings, and post-workshop debriefs, then sorted it into 20 themes. These would be pared down further to help us prioritize the best solutions and mitigate risk.

Themes identified during the analysis centered on configuration/installation, maintenance, and user experience. Configuration themes included **software configuration**, **PLC configuration**, upgrades, **Chemcassette installation**. Maintenance themes focused on **documentation quality**, **preventative maintenance**, spare parts management, valve performance, flow rate faults, **optics issues** and **training**. Finally, user-facing themes highlighted **HMI improvements**, **specific troubleshooting recommendations**, customer downtime and opportunities for Midas/Vertex integration.

With the workshop complete and key themes identified from pre-work with technical support tickets, stakeholder interviews, and the How Might We session, we now have clear priorities and initial solution paths to pursue. Themes such as documentation, configuration, custom recommendations, preventative maintenance, and PLC issues have emerged as core areas of focus. Next, we'll examine the note clusters around these themes to determine where to concentrate our efforts.

and DOD—revealed several usability and accessibility issues in their touchscreen interfaces. Poor color contrast, dense information layouts, and small touch targets make competitor screens difficult to operate and visually overwhelming.

Interpreting artifacts

Many artifacts from the engineering team were highly technical and difficult to follow, though ultimately very informative. I analyzed and translated these materials—ranging from specifications and process diagrams to test results—into clear, shareable frameworks and visual summaries. This helped cross-functional partners quickly grasp complex concepts and apply them effectively during design and development discussions.

Screen Analysis

Mapping the legacy Vertex screens helped to make sense of the decades old interface. Ahead of its time, the interface was designed prior to inventions like iPhone and iPad and the advent of touch interfaces. Therefore, trial and error and a reliance on training manuals were prerequisites for usage. Wireframing the legacy interface aided my understanding of the product by removing unnecessary colors. Patterns and a system of thought began to emerge.

Flows and process documentation

Mapping out flows with field service helped the team to better understand the steps involved when serious issues surrounding gas detection disrupted the FAB. Another key workflow introduced a differentiating feature for disabling auto pump swap and helped stakeholders visualize the functionality.

Wireframing

In this case wire framing really helped to reduce the noise on highly complex concepts. The engineers and design team were better able to focus on the process and the placement of key elements as we designed a pump maintenance system.

Usability testing with customers and internal stakeholders

As initial concepts crystalized the team, consisting of ID, research and UX, wanted to test out the validity with customer and stakeholders. Through this process we discovered that seeing green is calming and that focus mode color palette can mean something different within the staff at the fab. We tested step-by-step guidance, and the value of an AI assistant, all of which yielded surprising results. Lastly we wanted to test the value of analytics and how the visualization would be more valuable than the current table based event history.

WHAT IF...
Digital Interface with ECC, NDIR and Chemcassette

Full view w/ analyzer status, only highlighting points that require attention

Focus view to see alarm and gas details

Interaction and screen size preference preference? HMI, tablet, remote web interface

Overview Dashboard – Status Mode
Full overview with green status indicators was preferred.

Optional Icons – Assist Mode
Can be useful for training new hires, but would have to be disabled later

Overview Dashboard – Focus Mode
Gray points perceived as disabled or turned off. "Sleep mode" idea. Toggle option can help to switch modes based on user preference.

Status and Focus Toggle

Status	Focus
Color Indicators	Meaning
Green	Active
Red	Inactive or Faulty
Grayed Out	Disabled/Inhibited

Matt McGlothlin

Listening to feedback

From the early tech support ticket analysis to field service technicians and actual customers we heard that configuring the PLC was too cumbersome. So this was fixed with the one-of-a-kind PLC touch configurator. It was almost a gamification of a mundane and complex task. The idea came from selecting seats in a stadium when purchasing a ticket and mapping that to the number of people attending. What options do they want with for their seats and who should be notified.

Analytics and Event History

We also heard that field service technicians wanted more insights into faults and alarms on the Vertex. So we provided easy to digest visualizations that also helped with the quarterly reporting process for customers. The resulting savings could amount to \$1M+ annually and increase revenue for Honeywell in the high tech space.

Training and guided maintenance

We heard repetitively that documentation was lacking and that training was needed. We solved this by explicitly detailing the steps of complex tasks like replacing Chemcassettes while providing instant and

Runtime Operation

Matt McGlothlin

spend more time with the customer and less time figuring out how to troubleshoot edge case issues. The digital twin aspect of the diagnostics section received applause from sales, marketing and technicians.

"With the analytics and diagnostics ... This is something we can sell" - Honeywell High Tech President

Prototype

The prototype helped to test the final screens with users and internal stakeholders alike. Every screen was linked up to the prototype and we were able to hook it into a tablet that mimicked the actual Vertex machine.

During the dev handoff process it's critical to keep designs updated when there will inevitable be minor tweaks. This is why I implemented a versioning system that included branch and merge functionality similar to GitHub. This native-Figma functionality allowed designers and developers to stay in sync and schedule updates after release in subsequent sprints. Annotating designs is another critical and often overlooked part of the design process. Annotations reduce the amount of back and forth between developers and stakeholders alike.

Keep going and going ...

Successful products and upgrades don't happen overnight or even on the first release. There will always be feedback that designers didn't consider or hear about until after the release. There will be more ways to increase revenue after each successful release as customers see tremendous value in premium features.

That's the idea behind the new Vertex. Not only do we have plans to release an integration with customer application ecosystems but we also plan to introduce remote management and more AI-based features like more predictive analytics and integrating with Honeywell's gas portfolio and seeing where synergies can lie between Honeywell's extremely diverse product offerings.
